

# Python Programming: An Introduction to Computer Science

## Chapter 3 Computing with Numbers

## Objectives

- To understand the concept of data types.
- To be familiar with the basic numeric data types in Python.
- To understand the fundamental principles of how numbers are represented on a computer.

## Objectives (cont.)

- To be able to use the Python math library.
- To understand the accumulator program pattern.
- To be able to read and write programs that process numerical data.

## Numeric Data Types

- The information that is stored and manipulated by computer programs is referred to as *data*.
- There are two different kinds of numbers!
  - (5, 4, 3, 6) are whole numbers – they don't have a fractional part
  - (.25, .10, .05, .01) are decimal fractions

## Numeric Data Types

- Inside the computer, whole numbers and decimal fractions are represented quite differently!
- We say that decimal fractions and whole numbers are two different *data types*.
- The data type of an object determines what values it can have and what operations can be performed on it.

## Numeric Data Types

- Whole numbers are represented using the *integer* (*int* for short) data type.
- These values can be positive or negative whole numbers.

## Numeric Data Types

- Numbers that can have fractional parts are represented as *floating point* (or *float*) values.
- How can we tell which is which?
  - A numeric literal without a decimal point produces an int value
  - A literal that has a decimal point is represented by a float (even if the fractional part is 0)

## Numeric Data Types

- Python has a special function to tell us the data type of any value.

```
>>> type(3)
<type 'int'>
>>> type(3.1)
<type 'float'>
>>> type(3.0)
<type 'float'>
>>> myint = -32
>>> type(myint)
<type 'int'>
>>> myfloat = 32.0
>>> type(myfloat)
<type 'float'>
>>> mystery = myint * myfloat
>>> type(mystery)
<type 'float'>
```

## Numeric Data Types

- Why do we need two number types?
  - Values that represent counts can't be fractional (you can't have 3 ½ quarters)
  - Most mathematical algorithms are very efficient with integers
  - The float type stores only an *approximation* to the real number being represented!
  - Since floats aren't exact, use an int whenever possible!

## Numeric Data Types

- Operations on ints produce ints, operations on floats produce floats.

```
>>> 3.0+4.0
7.0
>>> 3+4
7
>>> 3.0*4.0
12.0
>>> 3*4
12
>>> 10.0/3.0
3.3333333333333335
>>> 10/3
3
>>> 10%3
1
>>> abs(5)
5
>>> abs(-3.5)
3.5
```

## Numeric Data Types

- Integer division **always** produces an integer, discarding any fractional result.
- That's why  $10/3 = 3!$
- Think of it as 'gozinta', where  $10/3 = 3$  since 3 gozinta (goes into) 10 3 times (with a remainder of 1)
- $10\%3 = 1$  is the remainder of the integer division of 10 by 3.

## Numeric Data Types

- Now you know why we had to use 9.0/5.0 rather than 9/5 in our Celsius to Fahrenheit conversion program!
- $a = (a/b)(b) + (a\%b)$

## Using the Math Library

- Besides (+, -, \*, /, \*\*, %, abs), we have lots of other math functions available in a *math library*.
- A *library* is a module with some useful definitions/functions.

## Using the Math Library

- Let's write a program to compute the roots of a quadratic equation!

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

- The only part of this we don't know how to do is find a square root... but it's in the math library!

## Using the Math Library

- To use a library, we need to make sure this line is in our program:  
*import math*
- Importing a library makes whatever functions are defined within it available to the program.

## Using the Math Library

- To access the sqrt library routine, we need to access it as *math.sqrt(x)*.
- Using this dot notation tells Python to use the sqrt function found in the math library module.
- To calculate the root, you can do `discRoot = math.sqrt(b*b - 4*a*c)`

## Using the Math Library

```
# quadratic.py
# A program that computes the real roots of a quadratic equation.
# Illustrates use of the math library.
# Note: This program crashes if the equation has no real roots.

import math # Makes the math library available.

def main():
    print "This program finds the real solutions to a quadratic"
    print
    a, b, c = input("Please enter the coefficients (a, b, c): ")
    discRoot = math.sqrt(b * b - 4 * a * c)
    root1 = (-b + discRoot) / (2 * a)
    root2 = (-b - discRoot) / (2 * a)

    print
    print "The solutions are:", root1, root2

main()
```

## Using the Math Library

```
This program finds the real solutions to a quadratic
Please enter the coefficients (a, b, c): 3, 4, -1
The solutions are: 0.215250437022 -1.54858377035
```

- What do you suppose this means?

```
This program finds the real solutions to a quadratic
Please enter the coefficients (a, b, c): 1, 2, 3
Traceback (most recent call last):
  File "<pyshell#26>", line 1, in <level>-
    main()
  File "C:\Documents and Settings\Terry\My Documents\Teaching\W04\CS
120\Textbook\code\chapter3\quadratic.py", line 14, in main
    discRoot = math.sqrt(b * b - 4 * a * c)
ValueError: math domain error
>>>
```

## Math Library

- If  $a = 1$ ,  $b = 2$ ,  $c = 3$ , then we are trying to take the square root of a negative number!
- Using the `sqrt` function is more efficient than using `**`. How could you use `**` to calculate a square root?

## Accumulating Results: Factorial

- Say you are waiting in a line with five other people. How many ways are there to arrange the six people?
- $720$  --  $720$  is the factorial of 6 (abbreviated  $6!$ )
- Factorial is defined as:  
$$n! = n(n-1)(n-2)\dots(1)$$
- So,  $6! = 6*5*4*3*2*1 = 720$

## Accumulating Results: Factorial

- How we could we write a program to do this?
- Input number to take factorial of,  $n$   
Compute factorial of  $n$ , `fact`  
Output `fact`

## Accumulating Results: Factorial

- How did we calculate  $6!$ ?
- $6*5 = 30$
- Take that  $30$ , and  $30 * 4 = 120$
- Take that  $120$ , and  $120 * 3 = 360$
- Take that  $360$ , and  $360 * 2 = 720$
- Take that  $720$ , and  $720 * 1 = 720$

## Accumulating Results: Factorial

- What's really going on?
- We're doing repeated multiplications, and we're keeping track of the running product.
- This algorithm is known as an *accumulator*, because we're building up or *accumulating* the answer in a variable, known as the *accumulator variable*.

## Accumulating Results: Factorial

- The general form of an accumulator algorithm looks like this:  
Initialize the accumulator variable  
Loop until final result is reached  
update the value of accumulator variable

## Accumulating Results: Factorial

- It looks like we'll need a loop!

```
fact = 1
for factor in [6, 5, 4, 3, 2, 1]:
    fact = fact * factor
```

- Let's trace through it to verify that this works!

## Accumulating Results: Factorial

- Why did we need to initialize fact to 1? There are a couple reasons...
  - Each time through the loop, the previous value of fact is used to calculate the next value of fact. By doing the initialization, you know fact will have a value the first time through.
  - If you use fact without assigning it a value, what does Python do?

## Accumulating Results: Factorial

- Since multiplication is associative and commutative, we can rewrite our program as:

```
fact = 1
for factor in [2, 3, 4, 5, 6]:
    fact = fact * factor
```

- Great! But what if we want to find the factorial of some other number??

## Accumulating Results: Factorial

- What does *range(n)* return?  
0, 1, 2, 3, ..., n-1
- range has another optional parameter!  
*range(start, n)* returns  
start, start + 1, ..., n-1
- But wait! There's more!  
*range(start, n, step)*  
start, start+step, ..., n-1

## Accumulating Results: Factorial

- Let's try some examples!

```
>>> range(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> range(5, 10)
[5, 6, 7, 8, 9]
>>> range(5, 10, 2)
[5, 7, 9]
```

## Accumulating Results: Factorial

- Using this souped-up *range* statement, we can do the range for our loop a couple different ways.
  - We can count up from 2 to n:  
`range(2, n+1)`  
(Why did we have to use n+1?)
  - We can count down from n to 1:  
`range(n, 1, -1)`

## Accumulating Results: Factorial

- Our completed factorial program:

```
# factorial.py
# Program to compute the factorial of a number
# Illustrates for loop with an accumulator

def main():
    n = input("Please enter a whole number: ")
    fact = 1
    for factor in range(n,1,-1):
        fact = fact * factor
    print "The factorial of", n, "is", fact

main()
```

## The Limits of Int

- What is 100!?

```
>>> main()
Please enter a whole number: 100
The factorial of 100 is
93326215443944152681699238856266700490715968264
38162146859296389521759999322991560894146397615
65182862536979208272237582511852109168640000000
0000000000000000
```

- Wow! That's a pretty big number!

## The Limits of Int

- Newer versions of Python can handle it, but...

```
Python 1.5.2 (#0, Apr 13 1999, 10:51:12) [MSC 32 bit (Intel)] on win32
Copyright 1991-1995 Stichting Mathematisch Centrum, Amsterdam
>>> import fact
>>> fact.main()
Please enter a whole number: 13
13
12
11
10
9
8
7
6
5
4
Traceback (innermost last):
  File "<pyshell#1>", line 1, in ?
    fact.main()
  File "c:\PYTHON-1\PYTHON-1.2\fact.py", line 5, in main
    fact=fact*factor
OverflowError: integer multiplication
```

## The Limits of Int

- What's going on?

- While there are an infinite number of integers, there is a finite range of ints that can be represented.
- This range depends on the number of *bits* a particular CPU uses to represent an integer value. Typical PCs use 32 bits.

## The Limits of Int

- Typical PCs use 32 bits
- That means there are  $2^{32}$  possible values, centered at 0.
- This range then is  $-2^{31}$  to  $2^{31}-1$ . We need to subtract one from the top end to account for 0.
- We can test this with an old version of Python.

## The Limits of Int

```
Python 1.5.2 (#0, Apr 13 1999, 10:51:12) [MSC 32 bit (Intel)]
on win32
Copyright 1991-1995 Stichting Mathematisch Centrum, Amsterdam
>>> 2**30
1073741824
>>> 2**31
Traceback (innermost last):
  File "<pyshell#3>", line 1, in ?
    2**31
OverflowError: integer pow()
>>>
```

## The Limits of Int

- It blows up between  $2^{30}$  and  $2^{31}$  as we expected. Can we calculate  $2^{31}-1$ ?

```
>>> 2**31-1
Traceback (innermost last):
  File "<pysHELL#5>", line 1, in ?
    2**31-1
OverflowError: integer pow()
```

- What happened? It tried to evaluate  $2^{31}$  first!

## The Limits of Int

- We need to be more clever!
- $2^{31} = 2^{30} + 2^{30}$
- $2^{31}-1 = 2^{30}-1 + 2^{30}$
- We're subtracting one from each side!

```
>>> 2**30-1+2**30
2147483647
>>> 2147483647+1
Traceback (innermost last):
  File "<pysHELL#7>", line 1, in ?
    2147483647+1
OverflowError: integer addition
>>>
```

## The Limits of Int

- What have we learned?
  - The largest int value we can represent is 2147483647
- How do modern versions of Python handle this?

```
Python 2.3.3 (#51, Dec 18 2003, 20:22:39) [MSC
v.1200 32 bit (Intel)] on win32
Type "copyright", "credits" or "license()" for
more information.
>>> 2**40
1099511627776L
```

## Handling Large Numbers: Long Ints

- Does switching to *float* data types get us around the limitations of *ints*?
  - If we initialize the accumulator to 1.0, we get
- ```
>>> main()
Please enter a whole number: 15
The factorial of 15 is 1.307674368e+012
```
- We no longer get an exact answer!

## Handling Large Numbers: Long Ints

- Very large and very small numbers are expressed in *scientific* or *exponential notation*.
- 1.307674368e+012 means  $1.307674368 * 10^{12}$
- Here the decimal needs to be moved right 12 decimal places to get the original number, but there are only 9 digits, so 3 digits of precision have been lost.

## Handling Large Numbers: Long Ints

- Floats are approximations
- Floats allow us to represent a larger range of values, but with lower precision.
- Python has a solution, the *long int*!
- Long Ints are not a fixed size and expand to handle whatever value it holds.

## Type Conversions

- To fix this problem, tell Python to change one of the values to floating point:  
`average = float(sum)/n`
- We only need to convert the numerator because now Python will automatically convert the denominator.

## Type Conversions

- Why doesn't this work?  
`average = float(sum/n)`
- `sum = 22, n = 5, sum/n = 4, float(sum/n) = 4.0!`
- Python also provides *int()*, and *long()* functions to convert numbers into ints and longs.

## Type Conversions

```
>>> float(22/5)
4.0
>>> int(4.5)
4
>>> int(3.9)
3
>>> long(3.9)
3L
>>> float(int(3.9))
3.0
>>> int(float(3.9))
3
>>> int(float(3))
3
```

## Type Conversions

- The *round* function returns a float, rounded to the nearest whole number.

```
>>> round(3.9)
4.0
>>> round(3)
3.0
>>> int(round(3.9))
4
```
